## 115 1 INTRODUCTION

116 Supply chains and consumers are demanding foods with lower **carbon footprints**  
117 (CF), that remain safe to consume, in recognition of the need to address climate  
118 change. The dairy industry is responding to these demands by adopting technologies  
119 that reduce greenhouse gas (**GHG**) emissions from dairy production and it is  
120 expected that new technologies will continue to be developed. Confidence that **GHG**  
121 **emissions reductions** are accurately quantified is required for CF claims associated  
122 with the implementation of a mitigation **technology** to be accepted by supply chains  
123 and consumers. This confidence can be provided by the global dairy industry  
124 adopting a consistent approach to objectively assess the robustness of mitigation  
125 technologies, and a **conservative** approach to estimating the **emissions reductions**  
126 that occur. This protocol set out criteria and approaches that, when applied to a  
127 **GHG** mitigation **technology**, will provide confidence to consumers and the supply  
128 chain that the claimed **GHG emissions reductions** are robustly validated and their  
129 products are safe to consume.

130

131 The protocol provides guidance on determining whether a mitigation **technology** has  
132 adequate **evidence** to support its adoption by the dairy industry and the integration  
133 of the **GHG emissions reduction** associated with the implementation of the  
134 **technology** into a CF calculator. The **GHG emissions reductions** can also be  
135 calculated manually if required. The approach to assessing the robustness of  
136 mitigation technologies and **conservatively** estimating the **GHG emissions reduction**  
137 that can be claimed was developed to act as a foundation upon which a standardised  
138 approach to the provision of robust **GHG emissions reductions** could be developed  
139 for all livestock sectors.

140

141 There are numerous initiatives developing guidance to ensure that quantification of  
142 **GHG emissions** and **emissions reductions** in livestock sectors are robust. This  
143 protocol has been developed to integrate the concepts of **technology** efficacy with  
144 the quantification of an **emissions reduction** associated with the implementation of  
145 the **technology** and has drawn on the knowledge provided by members of other  
146 known initiatives to identify areas of complementarity. The protocol is a live  
147 document that will be updated as initiatives deliver results that are relevant to the  
148 objectives of the protocol and that, when integrated, improve the robustness of  
149 protocol outcomes.

150

151 This protocol is suitable to assess technologies as described in the definitions (section  
152 3). It is not suitable to assess the **GHG emissions reductions** associated with changes  
153 to dairy management practices that deliver **emissions reductions** that are captured  
154 with existing **GHG emissions** calculations, such as through changes in herd  
155 productivity. The protocol does not include guidance on incorporating **carbon**  
156 **sequestration** in the CF of milk production; guidance for this is provided in the C seq  
157 guidelines (IDF, 2022a). Where a statistical regression approach (section 9.2.2) is  
158 used to calculate an **emissions reduction**, the protocol will require the calculation of  
159 a **prediction interval**. Determining the correct approach to generate a **prediction**  
160 **interval** may require the services of a statistician or biometrician.

161 The protocol consists of the main document and includes appendices with worked  
162 examples for two existing technologies as appendices and recommendations for  
163 future research that arose from the development of the protocol.

164 The following terminology is used throughout and is applicable to requirements with  
165 which protocol users need to comply:

- 166 - “shall” is used to indicate a requirement (mandatory).
- 167 - “should” is used to indicate a recommendation.
- 168 - “may” is used to indicate permission.
- 169 - “can” is used to indicate possibility.

## 170 2 PROTOCOL USE

171 The protocol provides guidance and requirements to quantify the **GHG emissions**  
172 **reduction** that can be claimed when a mitigation **technology** is implemented in a  
173 dairy system. It is applicable to mitigation technologies that can be implemented on  
174 dairy farms that target **GHG** sources such as **enteric methane**, on-farm fertiliser use  
175 and effluent management. The protocol is designed to be used in conjunction with  
176 the International Dairy Federation (IDF) CF guidance, “The IDF global **Carbon**  
177 **Footprint** standard for the dairy sector” (IDF, 2022b) and can also be applied to  
178 other methodologies and calculators. It provides guidance on the integration of the  
179 **emissions reduction** into a CF calculation. This is achieved by the calculation of the  
180 adjustment factor  $GHG_{adj_{t(0.6)}}$  that is multiplied with the **GHG emissions** for a  
181 nominated source, as calculated by an existing CF methodology, to provide an  
182 adjusted estimate of **GHG emissions** for that source. This estimate can then then be  
183 integrated into a CF calculation.

184

185 The application of the protocol shall address five elements:

- 186 i. Description of the **technology** and implementation **context** (section 5)  
187 including the type, name and use of the **technology**.
- 188 ii. Demonstration of product safety (section 6) including regulatory approvals  
189 and consideration of the potential for any adverse environmental, animal

- 190 welfare, dairy **product quality** or human health consequences from the  
191 production or use of the **technology**.
- 192 iii. Collation of multiple pieces of **evidence** that supports the **technology** as an  
193 **emissions reduction** strategy (section 7)
- 194 iv. Assessment of quality of data used to estimate emissions (section 8)
- 195 v. Selection of **evidence** that is relevant to the system(s) being assessed as a  
196 basis for the calculation of an adjustment factor and the use of the **evidence**  
197 to calculate the adjustment factor (section 9).

198

199 A flow chart of the process is provided in APPENDIX A.

200

201 The protocol was written in the **context** of assessing **emissions reductions**  
202 retrospectively however it can be applied prospectively evaluate a **technology** prior  
203 to adoption or project the **GHG emissions reduction** that may result from  
204 implementation.

205

### 206 3 TERMS, DEFINITIONS AND ABBREVIATED TERMS

207

208 Terms in the glossary are bolded throughout the document for reference.

209

#### 210 **Abatement**

211 **GHG removals** by sinks and/or reduction in **GHG emissions** by sources

212

#### 213 **Baseline (Reference case)**

214 A reference that provides the basis for comparison. In this document it refers to the  
215 system without use of the mitigation **technology**.

216

#### 217 **Biomass**

218 Organic material excluding material that is fossilised or embedded in geological  
219 formations, including living and dead organic matter (trees, crops, grasses, plant  
220 litter, algae, animals, manure, and waste of biological origin).

221

#### 222 **Carbon**

223 The chemical element with the symbol C.

224

#### 225 **Carbon credit**

226 Tradeable certificate representing one tonne of carbon dioxide equivalents (CO<sub>2</sub>e) in  
227 **GHG** emission reductions, or **GHG removals**. **Carbon credits** are generated by **GHG**  
228 **abatement** projects and quantified relative to a **baseline**. **Carbon credits** are  
229 commonly purchased to offset **GHG** emission of the purchasing entity.

230

#### 231 **Carbon crediting scheme**

232 Buying and selling **carbon credits** generated by activities that reduce **GHG emissions**  
233 or achieve **GHG removals**. Emissions trading can occur in government markets (state,  
234 regional or national) and on the voluntary market. **Carbon credit** schemes commonly  
235 apply integrity criteria to ensure that the credits represent the stated **GHG**  
236 **abatement**. Integrity criteria commonly include, but are not limited to, the avoidance  
237 of double counting and **leakage**, use of appropriate baselines, additionality, and  
238 permanence or measures to address impermanence.

239

240

241

242

243 **Carbon dioxide (CO<sub>2</sub>)**

244 A naturally occurring greenhouse gas, that is also a by-product of burning fossil fuels  
245 (such as oil, gas and coal), of burning **biomass**, of land use changes and of industrial  
246 processes (e.g., cement production). It is the principal anthropogenic greenhouse gas  
247 that affects the Earth's radiative balance. It is the reference gas against which other  
248 **GHGs** are measured and therefore has a Global Warming Potential (**GWP**) of 1.  
249 (Cowie et al., 2023)

250

251 **Carbon dioxide equivalent (CO<sub>2</sub>-e)**

252 Unit for comparing the radiative forcing of a **GHG** to that of carbon dioxide. The  
253 carbon dioxide equivalent is calculated as the mass of a given **GHG** multiplied by its  
254 global warming potential.(Cowie et al., 2023)

255

256 **Carbon footprint**

257 Sum of **GHG emissions** minus **GHG removals** of the subject expressed as carbon  
258 dioxide equivalents (CO<sub>2</sub>-e). The subject could be a product or an organisation.  
259 Where the subject is an organisation, such as a company, the CF often includes  
260 **Indirect emissions** also known as **scope 2** and **scope 3** emissions. Where the subject  
261 is a product, the CF includes the emissions and removals across the product life cycle.  
262 (Cowie et al., 2023) For farm products, a partial CF is often calculated, covering the  
263 life cycle stages up to the farm gate, or factory gate in the case of dairy products.

264

265 **Carbon neutrality**

266 Condition in which anthropogenic **GHG emissions** associated with a subject are  
267 balanced by anthropogenic **GHG removals**. The subject can be an entity such as a  
268 country, an organisation, a district or a commodity, or an activity such as a service or  
269 an event.

270

271 **Carbon sequestration**

272 The process of removing carbon dioxide from the atmosphere and transferring it to a  
273 carbon pool such as vegetation, soil, ocean or geological formation. (Cowie et al.,  
274 2023)

275

276 **Claimable emissions reduction**

277 Reduction in **GHG emissions** that can be claimed due to implementation of a  
278 **technology** as calculated by subtracting the adjusted **GHG emissions** calculated by  
279 this protocol from the estimated **GHG emissions** without the implementation of the  
280 **technology**.

281 **Conservative** (in this protocol)  
282 Claimable **GHG emissions** reduction that is less than the mean **GHG emissions**  
283 reduction from experimental results.  
284  
285 **Context** (in this protocol)  
286 The system in which the **technology** is intended to be applied. Includes the  
287 geography and feeding pattern (*i.e.* total mixed ration or pasture-based).  
288  
289 **Data quality**  
290 Relevance of the data used in emissions reductions calculations to the system being  
291 assessed. Includes the source of the data, system representativeness, temporal  
292 suitability, and geographical suitability.  
293  
294 **Emissions**  
295 See **Greenhouse Gas Emissions**  
296  
297 **Emissions reduction**  
298 A decrease in **GHG emissions** when compared to business-as-usual  
299  
300 **Enteric methane**  
301 **Methane** formed during the digestion process of ruminant animal species such as  
302 cattle, sheep, goats, etc. Microorganisms (bacteria, archaea, fungi, protozoa and  
303 viruses) present in the fore-stomach (reticulorumen or rumen) breakdown plant  
304 Biomass to produce substrates that can be used by the animal for energy and growth  
305 with **enteric methane** produced as a by-product. Fermentation end-products such as  
306 hydrogen, carbon dioxide, formate and methyl-containing compounds are important  
307 substrates for the production of **methane** by the rumen's **methane**-forming archaea  
308 (known as methanogens).  
309  
310 **Estimation**  
311 A value that has been obtained without measurement. A qualified **estimation** is one  
312 that has been made by a person with relevant expertise in the form of formal  
313 qualifications and experience. An unqualified **estimation** is one that has been made  
314 by a person without the relevant expertise in the form of formal qualifications and  
315 experience.  
316  
317 **Evidence**  
318 See **Piece of evidence**

319 **Experiment** (in this protocol)

320 A scientific procedure undertaken to compare the impacts of a **technology** (in this  
321 protocol) on the **GHG emissions** from a **farming system**(in this protocol). A  
322 treatment group compared to a control group constitutes 1 **experiment**; more than  
323 one **experiment** can be included in a single publication.

324

325 **Farming system**(in this protocol, also 'system')

326 The set of components and management that produces dairy products, including, the  
327 facilities, animals, and feed base, as listed in Section 5.1.3.

328

329 **Global warming potential (GWP)**

330 An index measuring the radiative forcing following an emission of a unit mass of a  
331 **GHG**, accumulated over a chosen time horizon, relative to that of the reference  
332 substance, carbon dioxide (CO<sub>2</sub>). The **GWP** represents the combined effect of the  
333 differing times that **GHGs** remain in the atmosphere and their different effectiveness  
334 in causing radiative forcing, that is, in heating the Earth's atmosphere. **GWP** is  
335 measured in units of carbon dioxide equivalents (CO<sub>2</sub>e). The most common time  
336 horizon is 100 years (**GWP100**).

337

338 Parties to the **UNFCCC** have agreed to use **GWP100** values from the **IPCC's** Fifth  
339 Assessment Report (AR5) or **GWP100** values from a subsequent **IPCC** Assessment  
340 Report to report aggregate emissions and removals of **GHGs** under the Paris  
341 Agreement.

342

343 **GHG**<sub>adj<sub>t(0.6)</sub></sub>

344 A decimal number between 0 – 1. It is a factor calculated by the use of the protocol  
345 and is multiplied by the baseline **GHG emissions** for the relevant source as calculated  
346 using a relevant existing **GHG accounting** framework. This provides an estimate of  
347 the **GHG emissions** for that source when the **technology** is implemented in a dairy  
348 system.

349

350 **Greenhouse gas (GHG)**

351 Gaseous constituent of the atmosphere, either natural and anthropogenic, that  
352 absorbs and emits radiation at specific wavelengths within the spectrum of thermal  
353 infrared radiation emitted by the Earth's surface, by the atmosphere itself, and by  
354 clouds. This property causes the greenhouse effect. Water vapor (H<sub>2</sub>O), carbon  
355 dioxide (CO<sub>2</sub>), nitrous oxide (N<sub>2</sub>O), **methane** (CH<sub>4</sub>), and ozone (O<sub>3</sub>) are the primary  
356 greenhouse gases in the Earth's atmosphere. Human-made **GHGs** include

357 sulphur hexafluoride (SF<sub>6</sub>), hydrofluorocarbons (HFCs), chlorofluorocarbons (CFCs)  
358 and perfluorocarbons (PFCs).

359

### 360 **Greenhouse gas accounting (GHG accounting)**

361 The process of compiling a chart of accounts that reports the inventory of **GHG**  
362 emissions, detailing the emissions and removals of each **GHG**, from each source and  
363 **sink** process, over a specified period, typically one year. For agricultural systems, that  
364 are often subject to wide annual variation, the data are often derived by averaging  
365 over a period of five or ten years.

366

### 367 **Greenhouse gas emissions (GHG emissions or emissions)**

368 Release of a **GHG** into the atmosphere; **GHG emissions** result from a **GHG** source

369

### 370 **Greenhouse gas removals (GHG removals)**

371 Anthropogenic activities that remove carbon dioxide from the atmosphere and  
372 durably store it in geological, terrestrial or ocean reservoirs, or in products. Carbon  
373 dioxide removal methods include afforestation, reforestation, biochar, bioenergy  
374 with carbon dioxide capture and storage (BECCS), soil **carbon sequestration**,  
375 enhanced weathering, direct air carbon capture and storage (DACCS), ocean  
376 alkalisation and ocean fertilisation. A carbon dioxide removal activity initiates a **sink**  
377 process that leads to **GHG removals**.

378

### 379 **Indirect emissions**

380 **GHG emissions** that are a consequence of the organisation's activities, but that arise  
381 from **GHG** sources that are not owned or controlled by the organisation. **Indirect**  
382 **emissions** occur upstream and/or downstream of the farm, across the value chain,  
383 and include emissions from manufacture of inputs such as fertiliser, and from  
384 processing of products, such as abattoir operations or milling. **Indirect emissions** also  
385 include emissions outside the value chain that are induced by change in demand for  
386 (or supply of) products produced or sourced by the organisation.

387

### 388 **International Panel on Climate Change (IPCC)**

389 An intergovernmental body of the United Nations established in 1988 to provide

390 scientific information on anthropogenic climate change, including the impacts and  
391 risks, and response options. The **IPCC** does not conduct original research but rather  
392 undertakes periodic, systematic reviews of published literature. **IPCC** reports are  
393 prepared by thousands of scientists and other experts who volunteer to assess the  
394 science related to climate change. The **IPCC** is governed by its member states  
395 through an elected bureau of scientists, who select the authors for each report from  
396 nominations received from governments and observer organisations.

397

### 398 **Leakage**

399 An increase in emissions that results indirectly from mitigation actions. **Leakage** can  
400 include increased **GHG emissions** upstream or downstream in the value chain (such  
401 as increased emissions associated with the implementation of a **technology**), or  
402 through market-mediated effects (such as indirect land use change to produce a  
403 commodity elsewhere, in response to a decline in production in the system being  
404 assessed).

405

### 406 **Life cycle assessment (LCA)**

407 Compilation and evaluation of the inputs, outputs and the potential environmental  
408 impacts of a product system throughout its life cycle.

409 Life cycle refers to “cradle-to-grave”: the consecutive and interlinked stages, from  
410 raw material acquisition or generation from natural resources to final disposal or  
411 recycling. In **LCA** of farm products, partial **LCA** is common, often covering cradle to  
412 farm gate.

413

### 414 **Meta-analysis**

415 A statistical analysis of the results of several experiments (in this protocol)

416

### 417 **Methane**

418 A potent greenhouse gas with short atmospheric lifetime. **Methane** is the major  
419 constituent of natural gas. Livestock production and paddy rice are significant  
420 **methane** sources. **Methane** is produced naturally when organic matter decays under  
421 anaerobic conditions, such as in wetlands.

422

### 423 **Mode of action** (in this protocol)

424 The physical, biological and/or chemical process that result/s in a reduction in **GHG**  
425 emissions

426

427

428 **Piece of evidence**

429 Can refer to either a set of experimental results, with multiple pieces of evidence  
430 able to be presented in one publication, a **meta-analysis** of a **technology**, or an  
431 existing methodology from an ICROA-accredited **carbon crediting scheme**.

432

433 **Prediction interval**

434 An estimate of an interval (*i.e.* upper and lower values) in which a prediction for a  
435 variable generated by populating an equation will fall, for a given probability.

436

437 **Primary data**

438 Quantitative measurement of activity from a product life cycle that is required to  
439 calculate **GHG emissions** or the reduction in emissions associated with a **technology**.  
440 For example, amount of chemical added to effluent or diet quality factors that can  
441 influence efficacy of feed additives.

442

443 **Product quality**

444 The quality of milk that is produced in a dairy in which a **technology** has been  
445 implemented. Refers to debris and sediment, flavour, colour and odour, bacterial  
446 count, existence of introduced chemicals, and composition and acidity.

447

448 **Reporting period** (in this protocol)

449 The period for which the **carbon footprint** of the **farming system** is being calculated.

450

451 **Scope 1, 2, 3 emissions**

452 Terminology developed by the Greenhouse Gas Protocol and now adopted broadly  
453 Scope 1 emissions: direct emissions arising from sources within the control of the  
454 reporting organisation.

455 Scope 2 emissions: **Indirect emissions** from the generation of purchased or acquired  
456 electricity, steam, heating or cooling consumed by the reporting organisation.

457 For farms, this is predominantly electricity use.

458 Scope 3 emissions: **Indirect emissions** other than scope 2 emissions that occur within  
459 the value chain as a consequence of the organisation's activities. For farms, scope 3  
460 emissions are the pre-farm and post-farm emissions, such as from manufacture of  
461 urea and herbicides, processing in abattoirs, and refrigerated transport of produce.

462

463

464

465 **Secondary data**

466 Data obtained from sources other than direct measurement of the **farming system**.  
467 Note that **secondary data** were used when **primary data** were not available or it is  
468 impractical to obtain **primary data**. **Secondary data** *should* also be based on peer-  
469 reviewed scientific literature, government statistics, or reports published by  
470 international institutions confirming the estimated value and associated uncertainty  
471 over multiple studies.

472

473 **Sink**

474 A process, activity or mechanism that removes a **GHG**, an aerosol or a precursor to a  
475 **GHG** from the atmosphere. A pool (reservoir) is a **sink** for atmospheric carbon if,  
476 during a given period, more carbon is moving into it than is flowing out.

477

478 **Source**

479 A process, activity or mechanism that releases a **GHG**, an aerosol or a precursor to a  
480 **GHG** into the atmosphere. Forests and agricultural lands are reservoirs: they can be  
481 either a **GHG source** or a **sink**.

482

483 **Technology** (in this protocol, also referred to as mitigation **technology**)

484 A product that reduces **GHG emissions** from a dairy farming system. The product can  
485 reduce **GHG emissions** via biological or chemical processes or can be a device.  
486 Examples of technologies include, but are not limited to, supplements to reduce  
487 **enteric methane** production, additives to reduce **GHG emissions** from effluent  
488 systems and coatings to reduce on-farm emissions associated with N fertiliser use. It  
489 specifically excludes products designed to sequester atmospheric C and the  
490 introgression of low-**methane** genetics into dairy herds.

491

492 **United Nations Framework Convention on Climate Change (UNFCCC)**

493 International treaty that aims to achieve the stabilization of greenhouse gas  
494 concentrations in the atmosphere at a level that would prevent dangerous  
495 interference with the climate system.

496

497 **Use** (in this protocol)

498 The process that is used to implement the **technology**, such as the rate and the  
499 frequency with which the **technology** is implemented and/or the period of time  
500 during the year that the **technology** is implemented.

501

## 502 4 ALIGNMENT WITH EXISTING STANDARDS

503 This protocol uses terminology and concepts that are consistent with **GHG** reporting  
504 and accounting at the corporate level, including for mandatory reporting, voluntary  
505 target-setting, environmental claims and the voluntary carbon market.

506 The protocol is designed to generate values that can be used in conjunction with CF  
507 calculators to enable the calculation of a reduced CF for products from dairies that  
508 have implemented a mitigation **technology**. Though it is designed to be integrated  
509 into CF calculations under the IDF **carbon footprint** standard (IDF, 2022b) it can also  
510 be applied in other CF or **LCA** tools. For example, it could be used in product level  
511 **carbon footprinting** using:

- 512 • Greenhouse Gas Protocol Product Life Cycle Accounting and Reporting  
513 Standard
- 514 • ISO 14067 **Carbon footprint** of products
- 515 • ISO 14068 **Carbon neutrality** (applied to a product).

516 The IDF standard provides comprehensive guidance on quantifying the **carbon**  
517 **footprint** of dairy products in accordance with the ISO **LCA** standards 14040 and  
518 14044. Topics covered include setting the system boundary, choosing the functional  
519 unit, handling co-products (allocation), data collection, and land use change, all of  
520 which are complex in the dairy sector, requiring tailored guidance. The IDF standard  
521 makes provision for the inclusion of mitigation technologies in CF calculations,  
522 recognising the need for **evidence** of efficacy, and specific guidance on  
523 quantification. This protocol is designed to address that need.

524 The protocol outputs could also be used by companies in preparing **GHG** inventories  
525 such as for voluntary claims related to **carbon neutrality**, **carbon footprint** reduction  
526 and net zero **GHG** targets, or for climate-related financial disclosure under the  
527 International Sustainability Standards Board (ISSB) standards and national  
528 equivalents, where consistent with the methodologies specified by these programs.  
529 The protocol could be used in conjunction with the following standards for corporate  
530 **GHG** reporting:

- 531 • Greenhouse Gas Protocol Corporate Standard
- 532 • Greenhouse Gas Protocol **Scope 3** Standard
- 533 • Greenhouse Gas Protocol Agricultural Guidance
- 534 • Greenhouse Gas Protocol Land Sector and Removals Guidance (to be released  
535 in Q3 or Q4, 2024)
- 536 • Science-based targets initiative (SBTi)
- 537 • ISSB IFRS S2 Climate-related disclosures

- 538 • ISO 14064-1 Organization level quantification and reporting of **GHG emissions**  
539 and removals
- 540 • ISO 14064-2 Project level quantification, monitoring and reporting of **GHG**  
541 emission reductions or removal enhancements
- 542 • ISO 14068 **Carbon neutrality** (applied to an organisation).  
543

544 The protocol generates qualitative information and data that could be used to  
545 support a product-based environmental claim such as under the ISO 14021,  
546 Environmental labels and declarations for self-declared claims, or ISO 14025  
547 Environmental labels and declarations Type III environmental declarations, for  
548 environmental product declarations (EPD).

549 The protocol requires information from a full life cycle assessment (**LCA**) that has  
550 been conducted in accordance with ISO 14040 and ISO 14044.

551 The IDF **carbon footprint** standard provides an overview of many of the standards  
552 and guidelines listed above, including their application to quantifying the **carbon**  
553 **footprint** of dairy products.

554

## 555 5 TECHNOLOGY AND IMPLEMENTATION CONTEXT

556 *How and where the **technology** will be implemented needs to be clearly stated to*  
557 *ensure information provided in the latter sections of the protocol is relevant to the*  
558 ***technology** and the specific implementation of the **technology** being assessed by the*  
559 *protocol.*

560

### 561 5.1 SCOPE

562 The scope of the **emissions reduction** assessment shall be defined by unambiguously  
563 describing the following:

564

- 565 i. The **technology** (see **Error! Reference source not found.**)
- 566 ii. The intended **use** of the **technology** (see 5.1.2)
- 567 iii. The system(s) in which the **technology** will be implemented (see 5.1.3)
- 568 iv. The period over which the **technology** will be implemented (see 5.1.4)

569

#### 570 5.1.1 TECHNOLOGY

571 A report prepared in accordance with this protocol shall unambiguously identify the  
572 **technology**. The identification of the **technology** shall include, where applicable, the

573 product name, trade name, manufacturer and/or active ingredient/s and/or the  
574 **mode of action**.

575

#### 576 5.1.2 USE

577 The **use** of the **technology** shall be described. This description shall contain the  
578 following information, where applicable: targeted **GHG** source, concentration or  
579 dosage, method of **use**, frequency of **use** and proportion of the **reporting period**,  
580 during which the **technology** will be used section 5.1.4. Where applicable, any  
581 requirements set out by the manufacturer with regards to the **use** of the **technology**  
582 (section **Error! Reference source not found.**) to achieve **emissions reductions** shall  
583 be attached to the report and shall be included in the description of **use**.

584

#### 585 5.1.3 SYSTEM

586 The system in which the **technology** was implemented shall be described. This  
587 description shall contain, where applicable, the following information:

- 588 i. Location, including climate and soil type
- 589 ii. Breed, including weight
- 590 iii. Whether the herd is self-replacing
- 591 iv. Productivity (e.g. fat and protein corrected milk production)
- 592 v. The proportion of the year the animals are housed
- 593 vi. The type of manure management system (required for manure  
594 management technologies only)
- 595 vii. The composition of the diet by season or month (*i.e.* the proportion of the  
596 dry matter intake that is pasture, grain, silage and/or supplements)
- 597 viii. The quality of the diet

598

599 Where any information changes during the year due to seasonal conditions or the  
600 availability of inputs (*e.g.* a change in the quality of supplied feed), points (i) through  
601 (viii) shall be documented on a seasonal basis and/or for each change.

602

#### 603 5.1.4 IMPLEMENTATION PERIOD

604 The proportion of the **reporting period** (*i.e.* period for which the CF is being  
605 calculated) during which the **technology** was implemented and for which a **GHG**  
606 **emissions reduction** is being estimated shall be documented.

## 607 6 SAFETY

608 *The acceptance of mitigation technologies by policy makers, industry and consumers*  
609 *requires demonstrating that the **technology** is safe to use, with respect to impacts on*  
610 *human health, animal health and the environment. This section provides minimum*  
611 *criteria that must be met by technologies to provide confidence that the*  
612 *implementation of the **technology** will have minimal adverse impacts. The*  
613 *assessment of environmental impacts under section 6.2 has been adapted from*  
614 *global frameworks on life cycle assessment including ISO-14044.*

615

### 616 6.1 REGULATORY APPROVALS

617 Written **evidence** of regulatory approval for the **technology** (**Error! Reference source**  
618 **not found.**) used as described (5.1.2) in the system (5.1.3) shall be attached to the  
619 report. This includes approvals by the appropriate organisations for commercial use  
620 of the **technology** as well as occupational health and safety regulations for the  
621 **technology**.

622

### 623 6.2 ENVIRONMENTAL IMPACTS

624 Results from a **LCA** of the manufacture and use of the **technology** as described  
625 (5.1.2) in a system that shares the characteristics documented in (5.1.3) shall be  
626 presented. The **LCA** shall be compliant with ISO 14044 (International Organization for  
627 Standardization, 2019) including an independent review. The **LCA** shall provide the  
628 impacts as absolute values (characterisation) and relative to the current production  
629 system without the proposed **technology**.

630

631 The **LCA** shall include a comprehensive set of environmental indicators including but  
632 not limited to **GHG** emissions. Indicator selection shall be relevant to the product  
633 system. For example, if the **technology** affects productivity, then water scarcity  
634 (Boulay et al., 2018) and land use impacts on soil quality (Bos et al., 2020; Brandão et  
635 al., 2011) would be necessary. If the **technology** emits ozone depleting substances,  
636 then ozone depletion (World Meteorological Organization (WMO), 2014) would be  
637 required. Any **technology** based on a chemical additive should include human  
638 toxicity (cancer and non-cancer) (Fantke et al., 2021). Recommended indicators lists  
639 for different technologies is included in APPENDIX E.

640

641 As different indicators are not of equal importance it not practical to set thresholds of  
642 impact increase in non-greenhouse gas indicators which can be tolerated in a **GHG**  
643 **abatement technology**. What **LCA** can provide is transparent information on relative  
644 impact increases or decreases to ensure unintended impacts can be assessed by  
645 users of that **technology**. As such the risk of adverse environmental consequences  
646 shall be discussed as part of the protocol.

647

### 648 6.3 IMPACTS TO THE FARMING SYSTEM

649 Given that minimum standards of health and safety for both animals and humans  
650 have been addressed in Section 6.1 and the decisions regarding appropriate trade-  
651 offs vary on **context**, there is no threshold associated with farm impacts. What is  
652 required is a disclosure of the known information citing original peer-reviewed  
653 research and identification of knowledge gaps regarding impacts on production,  
654 **product quality**, and animal health and welfare. A list of all reviewed, original  
655 literature (i.e. not reviews) on these topics and the databases and search terms used  
656 to find these articles should be included.

657

658 This section shall review the consequences of using the **technology** on animal  
659 welfare and impact on product quality or production. If any of this information is not  
660 available, the information gap needs to be acknowledged. Where the  
661 implementation of a **technology** results in a decrease in production then the  
662 magnitude of the reduction shall be reported, due to the risk of **leakage** associated  
663 with a decrease. Changes in production also need to be captured in the CF  
664 calculation to reflect resulting changes in emissions per unit product.

## 665 7 DEMONSTRATING EFFICACY OF A TECHNOLOGY

666 *Confidence that the implementation of the **technology** will result in a consistent and*  
667 *reliable reduction in **GHG emissions** is important for the acceptance of claimed **GHG***  
668 ***emissions reductions** associated with implementation of that **technology**. This is*  
669 *achieved by providing **evidence** either as results from multiple scientific experiments*  
670 *that have demonstrated effectiveness of the **technology** or as a methodology*  
671 *approved under an existing accredited **Carbon crediting scheme**. Both forms of*  
672 ***evidence** have minimum requirements that must be met to ensure that the **evidence***  
673 *provided is robust, which are described in this section.*

674

675 *The more pieces of **evidence** available the greater the confidence in the assessment*  
676 *of a **technology** therefore, it is imperative that as many pieces of **evidence** as possible*  
677 *are provided to support assessment of the efficacy of the **technology**. However, the*  
678 *results of experiments are not always published or made available in the public*  
679 *domain. Therefore, the authors acknowledge that this protocol is limited by the*

680 *reality that generally only experiments showing a statistically significant positive or*  
681 *adverse effect of a treatment are published in scientific journals, and some*  
682 *experimental results are confidential, held by commercial companies.*

683

#### 684 7.1 DEMONSTRATED REPEATABLE REDUCTIONS

685 A consistent reduction in **GHG emissions** associated with the implementation of the  
686 **technology** shall be demonstrated using one of the following:

687

688 i. a **meta-analysis** demonstrating a statistically significant ( $P \leq 0.05$ ) **GHG**  
689 **emissions reduction** associated with the **use** of the **technology**, that meets  
690 the requirements for experimental settings and scientific publications  
691 specified in section 7.2. A copy of the publication shall be attached to the  
692 report if it is not open-access, and if it is open access, the digital object  
693 identifier (DOI) shall be provided.

694

695 ii. a minimum of three (3) experiments that:

696

697 a. demonstrate a statistically significant ( $P \leq 0.05$ ) reduction in **GHG**  
698 emissions, and

699

700 b. that meet the requirements for experimental settings and scientific  
701 publications specified in section 7.2

702 Copies of the scientific publication(s) containing results of these experiments shall  
703 be attached to the report if they are not open access and if they are open access,  
704 the DOI shall be provided.

705

706 iii. An existing methodology from a **Carbon crediting scheme** that meets the  
707 minimum requirements set out in section 7.2.2.

708

709 A statement shall be made for each **piece of evidence** outlining how the  
710 requirements in section 8.2 are met.

711

## 712 7.2 REQUIREMENTS FOR PIECES OF EVIDENCE

### 713 7.2.1 EXPERIMENTAL SETTINGS AND SCIENTIFIC PUBLICATIONS

714 Where a **meta-analysis** (8.1 option (i)) or set of experimental results (8.1 option (ii))  
715 are used as **evidence**, the protocol user shall justify that the experimental results are  
716 applicable to a commercial dairy situation.

717

718 Experimental results that have been published in a journal that was classified as a  
719 level 1 or 2 journal on the Norwegian Register For Scientific Journals, Series and  
720 Publishers at the time of publication shall be used as **evidence**. Documentation  
721 showing that the journal was a level 1 or 2 journal at the time of publication shall be  
722 attached to the report.

723

724 Experimental results from experiments that do not include a control shall not be  
725 used.

726

### 727 7.2.2 EXISTING METHODOLOGIES

728 Calculations from an approved **Carbon crediting scheme** methodology may be used  
729 to calculate the **claimable emissions reduction** (see 7.2.2). if

- 730 i. that methodology is from a standard endorsed by the International Carbon  
731 Reduction and Offsetting Accreditation (ICROA) program and  
732 ii. it provides a **conservative** estimate of **GHG emissions reduction** by using  
733 statistical uncertainty to adjust the **GHG emissions reduction**, and the  
734 estimate calculated using the methodology is as **conservative** as that  
735 calculated using this protocol, or data are provided that allow adjustment  
736 such that the estimate of **emissions reduction** can be adjusted to be as  
737 **conservative** as that calculated using this protocol.

## 738 8 DATA QUALITY

739 *The calculation of a claimable **GHG emissions reduction** requires data for a dairy  
740 production system. Data can be **primary data** (i.e. data that are specific to the system  
741 being assessed) or **secondary data** (i.e. data obtained from another system and  
742 applied to the system being assessed). **Secondary data** are lower quality data  
743 however in some instances **secondary data** may be the only data available to  
744 calculate the claimable **GHG emissions reduction**. Using lower quality data to  
745 calculate a **GHG emissions reduction** reduces the accuracy of the calculation and has  
746 the potential to reduce the acceptance by the target audience of **GHG emissions  
747 reduction** claims by the dairy sector. Adjusting the **claimable emissions reduction** for  
748 the quality of data used demonstrates to the target audience that the dairy sector  
749 acknowledges that using lower quality data impacts the confidence in the efficacy of*

750 *a **technology**. A **data quality** adjustment has a number of other benefits including*  
751 *incentivising the use of high-quality data to maximise the **claimable emissions***  
752 ***reduction** and ensuring the protocol is flexible enough to be applied to yet-to-be-*  
753 *developed technologies that may require data that is inherently difficult to obtain and*  
754 *will therefore by necessity be low-quality.*

755

756 *The approach to **data quality** used in the protocol is adapted from the data pedigree*  
757 *matrix approach used by the global life cycle assessment community (Ciroth et al.,*  
758 *2016). A factor with which to adjust a **claimable emissions reduction** is calculated*  
759 *based on the quality of data used to calculate the **claimable emissions reduction**. The*  
760 *integration of this factor adds statistical uncertainty to the equations used to*  
761 *calculate the **claimable emissions reduction** when data used is not of the highest*  
762 *possible quality. This increase in statistical uncertainty increases the **prediction***  
763 ***interval** resulting in a greater adjustment of the estimated **emissions reduction**.*

764

765 The quality of the data used to calculate an **emissions reduction** is determined by  
766 four categories as described below. The levels for each category are presented in  
767 APPENDIX and the **data quality** adjustment is described in sections 9.2.1 and 9.2.2.

768

769 i. DATA SOURCE

770 This criterion evaluates the quality of the data based on the method of obtaining the  
771 data. It assesses whether the data are obtained via direct measurements, a  
772 calculation or a qualified estimate.

773

774 ii. SYSTEM REPRESENTATIVENESS

775 This criterion assesses the extent to which the on-farm data used to estimate the  
776 **emissions reduction** represent the system being assessed. Data that are obtained  
777 from the system being assessed are considered higher quality than data that are  
778 obtained from other system or regional averages. Milk output per cow is used to  
779 determine representativeness because it reflects the system with respect to  
780 feedbase and livestock movement (*i.e.* barn systems with high quality feed and  
781 limited movement are likely to have higher productivity than a pasture-based system  
782 with lower quality feed where cows walk further, so use more energy).

783

784 iii. TEMPORAL SUITABILITY

785 This criterion evaluates the extent to which data are up-to-date and applicable and,  
786 therefore, relevant to the **reporting period** covering relevant events and trends.

787

788 iv. GEOGRAPHICAL SUITABILITY

789 Geographical suitability examines whether the data's geographic scope match the  
790 area of interest for the system being assessed. This ensures that the data are  
791 applicable to the specific location or region of concern.

792

793 8.1 DATA QUALITY ASSESSMENT

794 The data source and relevant **data quality** adjustment factor for each of the variables  
795 used to calculate **emissions reductions** shall be documented in a table. **Data quality**  
796 adjustment factors for each **data quality** category are given in APPENDIX B.

797

798 9 CALCULATION OF CLAIMABLE EMISSIONS REDUCTION

799 *Providing confidence that the **claimable emissions reduction** associated with the*  
800 *implementation of a **technology** is robustly validated is achieved using the following*  
801 *four strategies:*

802

803 1. *The use of robust scientific results from the **evidence** that is most relevant to*  
804 *the system under study as the basis for **GHG emissions reduction** calculations.*  
805 *The scientific **evidence** must meet requirements (7.2) and be relevant to the*  
806 ***technology** and **context** as described in section 5.*

807

808 2. *The calculation of a **conservative** estimate of the **GHG emissions reduction**,*  
809 *where the magnitude of the **emissions reduction** is adjusted according to the*  
810 *uncertainty of the experimental results to determine the **claimable emissions***  
811 ***reduction**. such that the emission reduction is reduced in proportion to*  
812 *uncertainty. This provides an incentive to **technology** developers and*  
813 *researchers to generate and publish high quality experimental results.*  
814 *Adjusting **GHG emissions reductions** based on statistical uncertainty is a*  
815 *relatively common approach to ensure the integrity of **GHG emissions***  
816 *reduction claims and is a basic principle of the Verra Carbon Standard*  
817 *(Standard, 2022) and is also included in government **carbon credit***  
818 *methodologies (Australian Government, 2021). In this protocol, the **claimable***  
819 ***emissions reduction** is the value for which there is 60% chance of exceedance.*

820

821 3. *The adjustment of the calculated **GHG emissions reduction** for the quality of*  
822 *data that is used to calculate the **emissions reduction**. Adjusting the calculated*  
823 ***GHG emissions reduction** for **data quality** incentivises the collection and use of*  
824 *the highest possible quality data from the system being assessed and provides*  
825 *flexibility in the data that can be used.*

826

827 4. *The estimated **GHG emissions reduction** is re-calculated on an annual basis or*  
828 *whenever new information that improves an estimate of **GHG emissions***  
829 ***reduction** becomes available.*

830

## 831 9.1 EVIDENCE USED FOR CALCULATIONS

832 The **evidence** used for calculations shall be one of either:

833

834 i. A **meta-analysis** that meets requirements set out in section 7.1.i.

835

836 ii. The provision of experimental results that demonstrate a significantly  
837 significant ( $P \leq 0.05$ ) reduction in **GHG emissions** when compared to a control  
838 for the **technology (Error! Reference source not found.)** when used (5.1.2) in  
839 a system as described (5.1.3). These experiments must meet the requirements  
840 as set out in section 7.1.ii.

841

842 iii. Where more than one set of experimental results have equal relevance to the  
843 system being assessed, as described above in 9.1.ii, and it is statistically  
844 appropriate to average the experimental results as determined by a qualified  
845 statistician, then the results shall be averaged and the average used to  
846 calculate an **emissions reduction**.

847

848 iv. An existing methodology from a **GHG abatement** scheme that meets the  
849 minimum requirements set out in section 7.2.2.

850

851 Where multiple pieces of **evidence** are available, the **evidence** that is the most  
852 relevant to the system being assessed shall be used.

853

854 If unrestricted online access is available, the DOI or other permanent digital identifier  
855 for the relevant document shall be provided. Otherwise, a copy of the relevant  
856 document shall be provided. Where multiple sets of experimental results are  
857 averaged, a report from a statistician detailing the method used to derive the  
858 average shall be provided.

859

860 **Evidence** shall only be used in calculations of **claimable emissions reduction** where  
861 these criteria are met:

862  
863  
864  
865  
866  
867  
868  
869  
870  
871  
872  
873  
874  
875  
876  
877  
878  
879  
880  
881  
882  
883  
884  
885  
886

901

- i. The implementation of the **technology** in the **evidence** used to calculate **claimable emissions reduction** shall be consistent with the implementation **context** described in section 5.1.2. The protocol shall not be used to assess the implementation of a **technology** where these uses are inconsistent. This includes, where relevant, the concentration declared under section 5.1.2.
- ii. Where the **evidence** used to calculate an **emissions reduction** is a regression equation, the values of data used to populate the equation to estimate the **emissions reduction** shall not exceed the range of values for the relevant variable used to develop the equation.
- iii. Where the **GHG emissions reduction** is dependent on the environmental conditions that change over time (*e.g.* on a seasonal basis), then a **GHG emissions reduction** shall only be calculated where the environmental conditions declared in section 5.1.2 are the same as those under which the **evidence** used to support calculation under section 9.1 were obtained.
- iv. Claims for a **GHG emissions reduction** should not exceed the maximum duration of the **experiment** in the **evidence** used as a basis for **GHG emissions reductions** calculations. It is common for biological systems and processes (*e.g.* using a chemical to change the activity of one group of microbes in an environment with a diversity of microbe groups) to adapt to changes. It is also likely that indications of adaptation will be observable over a period of months, as opposed to years. If the period of claim exceeds the maximum duration then the longer period of claim shall be justified. Justifying a longer period shall rely on published scientific literature and consider the **mode of action** for the **technology**, the vulnerability of the **technology** to adaptation and the absence of adaptation in **experiments** of a duration in which adaptation could be expected to occur.
- v. If the **evidence** comes from experiments conducted in a different system, or in the same system under different diet compositions (5.1.3), the user shall justify that the **evidence** used in calculation of **claimable emissions reduction** is applicable to the system under study. Justification is qualitative and shall address the following components (where relevant to the declared **technology**); animal mass, milk production, diet type, diet quality, climate, soil type (as described using the surface soil texture) and describe the proportion of year that that changes in any of these components occurs.

902 If used as **evidence**, an external **GHG abatement** scheme methodology shall be  
903 strictly limited to the **use/system** defined within the methodology.

904

905 A statement outlining how these criteria are met shall be provided.

906

#### 907 9.1.1 UNCERTAINTY ADJUSTMENT

908 Where a methodology from an existing **Carbon crediting scheme** is used, and the  
909 **emissions reduction** calculated by the methodology is less **conservative**, the  
910 calculations contained in the methodology shall be adjusted so the calculated  
911 **emissions reduction** is as **conservative** as that calculated using this protocol.

912

#### 913 9.2 EQUATIONS

914 *Statistical knowledge and/or an understanding of **prediction intervals** may be needed*  
915 *to undertake the calculations specified in this protocol, so the input of a statistician*  
916 *may be necessary to implement the protocol. The equations used to calculate the*  
917 *factor required to calculate the **claimable emissions reduction** are dependent on the*  
918 *statistical analysis used in the **evidence** (section 9.1). Where the calculation of **GHG***  
919 ***emissions reduction** uses the difference in absolute emissions between a control and*  
920 *treatment assessed by a parametric statistical method, a factor with which to*  
921 *calculate a **claimable emissions reduction** shall be calculated using equations in*  
922 *section 9.2.1. Where the **GHG emissions reduction** is calculated using an equation*  
923 *developed using a parametric statistical method, a factor with which to calculate a*  
924 ***claimable emissions reduction** shall be calculated using equations in section 9.2.2.*  
925 *Guidance when a non-parametric statistical method has been used is provided in*  
926 *9.2.3. It is difficult to provide specific equations for calculating the **claimable***  
927 ***emissions reduction** when an equation is used due to the different statistical analyses*  
928 *that can be used to generate an equation for calculating **emissions reductions**. As*  
929 *such, the equations presented here are high level and the application of the equations*  
930 *will likely require the input of a statistician or biometrician. Experimental data*  
931 *analysed using non-parametric analysis methods can also be used and requires a*  
932 *statistician to ensure the calculations used are appropriate.*

933

934 The protocol generates  $GHG_{adj_{t(0.6)}}$ , an adjustment factor expressed as a decimal  
935 that is used to adjust an estimate of **GHG emissions** from the relevant **GHG** source  
936 without the **technology** implemented as calculated by an existing CF methodology.

937

938 For all equations presented in this sub-section:

- 939 - Where a mixed model approach was used for statistical analysis in the  
940 **evidence** and random effects in the model were statistically significant then  
941 the predicted values shall be used.
- 942 - Where a co-variate was included in the statistical analysis in the **evidence** and  
943 found to be significant then values adjusted for co-variance shall be used.

944

#### 945 9.2.1 DIFFERENCE BETWEEN THE MEANS OF A CONTROL AND A TREATMENT

946 Where a statistically significant **GHG emissions reduction** is demonstrated between  
947 the control and a treatment, the factor,  $GHG_{adj_{t(0.6)}}$ , that is used to adjust the **GHG**  
948 **emissions** using a CF method may be calculated using Equation 1.  $GHG_{adj_{t(0.6)}}$  may  
949 alternatively be calculated via another method (e.g. Fieller's theorem) when the  
950 calculations are done by a qualified statistician. Those calculations shall include an  
951 adjustment for the specified probability of exceedance and be appropriately adjusted  
952 for DQ , and be attached in a report provided by the statistician.

953

954 *Equation 1*

$$955 \quad GHG_{adj_{t(0.6)}} = \frac{\bar{x}_c - x_a}{\bar{x}_c}$$

956

957 where  $GHG_{adj_{t(0.6)}}$  is the value used to adjust the emissions as calculated without the  
958 **technology**,  $\bar{x}_c$  is the sample mean of the control, from the **experiment** and  $x_a$  is the  
959 difference between the control and treatment groups adjusted for statistical  
960 uncertainty and **data quality** using Equation 2.

961

962 *Equation 2*

$$963 \quad x_a = \bar{x}_d + t_{(0.6,df)} \cdot \Delta_{diff}$$

964

965 where  $\bar{x}_d$  is the difference between the estimated means of the control and  
966 treatment groups as calculated using Equation 3,  $t_{(0.6)}$  is the critical lower one-tail  
967 value from the  $t$ -distribution for the relevant  $df$ , as calculated by Equation 4, based  
968 on a 60% confidence level and  $\Delta_{diff}$  is the adjusted uncertainty associated with the  
969 measurement of the control and treatment samples or populations as calculated  
970 using Equation 4.

971

972 *Equation 3*

$$973 \quad \bar{x}_d = \bar{x}_c - \bar{x}_t$$

974

975 where  $\bar{x}$  and  $\bar{x}_t$  are the means of the control and treatment groups, respectively, as  
976 taken from the **evidence** declared in section 9.1.

977

978 *Equation 4*

$$979 \quad df = \frac{(SE_{\bar{x}_c}^2 + SE_{\bar{x}_t}^2)^2}{\left(\frac{SE_{\bar{x}_c}^4}{df_{\bar{x}_c}} + \frac{SE_{\bar{x}_t}^4}{df_{\bar{x}_t}}\right)}$$

980

981 where  $SE_{\bar{x}_c}$  and  $SE_{\bar{x}_t}$  are the standard errors of  $\bar{x}_c$  and  $\bar{x}_t$ , respectively, from the  
982 **evidence** used to support the calculations in 9.1 and  $df_{\bar{x}_c}$  and  $df_{\bar{x}_t}$  are the degrees of  
983 freedom for the control and treatment groups.

984

985 *Equation 5*

$$986 \quad \Delta_{diff} = \sqrt{\overline{DQ} \cdot (SE_{\bar{x}_c}^2 + SE_{\bar{x}_t}^2)}$$

987

988 where  $\overline{DQ}$  is the adjustment for **data quality** as calculated using Equation 6 , and  
989  $SE_{\bar{x}_c}$  and  $SE_{\bar{x}_t}$  are as previously described.

990

991 *Equation 6*

$$992 \quad \overline{DQ} = \frac{\sum_{i=1}^n D_i + S_i + T_i + G_i}{n \times 4}$$

993

994 where  $D_i$ ,  $S_i$ ,  $T_i$  and  $G_i$  are the **data quality** scores for data source, system likeness,  
995 temporality and geography, respectively, taken from APPENDIX , for the data  
996 representing the  $i^{\text{th}}$  variable used to calculate the emissions from the **GHG** source  
997 nominated in section 5.1.2 using a CF calculator, and  $n$  is the number of variables  
998 that are used to calculate the **GHG emissions** from the nominated **GHG** source.

999

### 1000 9.2.2 REGRESSION APPROACH

1001 A regression approach refers to the prediction of an **emissions reduction** using an  
1002 equation that is developed using statistical analysis. When a regression approach is  
1003 used to estimate the **emissions reduction** associated with the implementation of a  
1004 **technology**, the **claimable emissions reduction** shall be calculated using the  
1005 appropriate equation below. Equations rely on the calculation of a **prediction**  
1006 **interval**, and the method to calculate the **prediction interval** is dependent on  
1007 characteristics of the equation (*e.g.* the numbers of dependent variables in the  
1008 equation) that is used as a basis for calculations, and it is the responsibility of the

1009 biometrician supporting the protocol user to determine the most appropriate  
1010 approach to calculating the **prediction interval**.

1011

1012 *Case 1 - Regression equation for a change in emissions relative to a control expressed*  
1013 *as a negative decimal or percentage.*

1014

1015 *Equation 7*

1016 
$$GHG_{adj_{t(0.6)}} = \frac{\hat{y}_{adj}}{r\%} + 1$$

1017

1018 Where the dependent variable is a negative value expressing the change in emissions  
1019 relative to a control (e.g. a 60% reduction in **GHG emissions** is represented by the  
1020 value of -60), then  $GHG_{adj_{t(0.6)}}$  shall be calculated using Equation 7. Where  $\hat{y}_{adj}$  is  
1021 the relevant **prediction interval** calculated using the critical value from the  $t$ -  
1022 distribution for the relevant  $df$  and a 60% confidence level, adjusted for **data quality**,  
1023 and  $r\%$  is 100 convert  $GHG_{adj_{t(0.6)}}$  to a decimal format where  $\hat{y}$  is a percentage or 1  
1024 in all other instances. Where Equation 7 is used to calculate  $GHG_{adj_{t(0.6)}}$  the  
1025 **prediction interval** that results in a value for  $\hat{y}_{adj}$  being greater than the value  
1026 for  $\hat{y}$  shall be used.

1027

1028 *Case 2 - Regression equation for a change in emissions relative to a control as a*  
1029 *positive decimal or percentage.*

1030

1031 *Equation 8*

1032 
$$GHG_{adj_{t(0.6)}} = 1 - \frac{\hat{y}_{adj}}{r\%}$$

1033

1034 Where the dependent variable is a positive value expressing the change in emissions  
1035 relative to a control (e.g. a 60% reduction in **GHG emissions** is represented by the  
1036 value of 60), then  $GHG_{adj_{t(0.6)}}$  shall be calculated using Equation 8 where  $\hat{y}_{adj}$  is the  
1037 relevant **prediction interval** calculated using the critical value from the  $t$ -distribution  
1038 for the relevant  $df$  and a 60% confidence level adjusted for **data quality** and  $r\%$  is  
1039 100 convert  $GHG_{adj_{t(0.6)}}$  to a decimal format where  $\hat{y}$  is a percentage or 1 in all other  
1040 instances. Where Equation 8 is used to calculate  $GHG_{adj_{t(0.6)}}$  the **prediction interval**  
1041 that results in a value for  $\hat{y}_{adj}$  being less than the value for  $\hat{y}$  shall be used.

1042

1043 Case 3 - Regression equation for **GHG** emitted relative to a control expressed as a  
1044 decimal or a percentage.

1045

1046 Equation 9

$$1047 \quad GHG_{adj_{t(0.6)}} = \frac{\hat{y}_{adj}}{r\%}$$

1048

1049 Where the dependent variable expresses the **GHG** emitted relative to a control (*i.e.* a  
1050 60% reduction in **GHG emissions** is represented by the value of 40) then  $GHG_{adj_{t(0.6)}}$   
1051 shall be calculated using Equation 9 where  $\hat{y}_{adj}$  is the relevant **prediction interval**  
1052 calculated using the critical value from the *t*-distribution for the relevant *df* and a  
1053 60% confidence level adjusted for **data quality** and  $r\%$  is 100 convert  $GHG_{adj_{t(0.6)}}$  to a  
1054 decimal format where  $\hat{y}$  is a percentage or 1 in all other instances. For Equation 9,  
1055 the **prediction interval** that results in a value for  $\hat{y}_{adj}$  being greater than the value  
1056 for  $\hat{y}$  shall be used.

1057

1058 Equation 10

$$1059 \quad DQ_i = \frac{D_i + S_i + T_i + G_i}{4}$$

1060

1061 where  $D_i$ ,  $S_i$ ,  $T_i$  and  $G_i$  are the **data quality** scores for data source, system likeness,  
1062 temporality and geography, respectively, taken from APPENDIX B for the  $i^{\text{th}}$  variable  
1063 used to populate the regression equation.

1064

1065 Where the approach allows for the **data quality** adjustment to be made for each  
1066 variable then the **data quality** for each variable shall be calculated using Equation 10  
1067 and applied to each variable within the square root function of  $\Delta_t$ , otherwise the  
1068 average **data quality** (Equation 6) shall be calculated and applied within the square  
1069 root function of  $\Delta_t$  (as demonstrated in APPENDIX D).

1070

### 1071 9.2.3 NON-PARAMETRIC STATISTICAL ASSESSMENT

1072 Where the reduction in **GHG emissions** associated with the implementation of a  
1073 **technology** was assessed using non-parametric statistical methods, the use of the  
1074 results from that analysis as a basis for calculating a claimable **GHG emissions**  
1075 **reduction** is permitted. The calculation of a claimable **GHG emissions reduction** shall  
1076 be done by a qualified statistician and shall use an approach that adjusts a mean  
1077 effect by the specified probability of exceedance, appropriately adjusted for DQ.

1078

1079 9.3 FREQUENCY OF CALCULATION

1080 The calculation shall be reviewed annually, when data used to calculate a **claimable**  
1081 **emissions reduction** changes or when experimental results that improve the  
1082 robustness of the adjustment factor are made available via publication in a relevant  
1083 scientific journal (see section 7.2).

1084

1085 10 MULTIPLE TECHNOLOGIES

1086 Where multiple technologies are implemented within the same system and each  
1087 **technology** reduces a different emissions source, then the protocol shall be applied  
1088 to each **technology** individually and each **GHG emissions** source adjusted using the  
1089 relevant protocol output. Where multiple technologies are implemented within the  
1090 same system and the technologies reduce the same emissions source, then sections  
1091 5 to 7 shall be completed for each **technology**. Sections 8 and 9 shall be completed  
1092 for the technologies combined (*i.e.* the **evidence** used to calculate **GHG emissions**  
1093 **reduction** shall be from experiments that implemented technologies  
1094 simultaneously).

1095

1096 11 REPORT

1097 To ensure transparency, a report shall be generated that provides the required  
1098 information as outlined in sections 5 to 9, with the headings of each section  
1099 corresponding to those used in this document. Example reports are presented in  
1100 APPENDIX C and APPENDIX D. The information provided shall be suited for the  
1101 intended use of the protocol outputs. For example, the worked examples presented  
1102 are for a single dairy, with the system description providing detail for that dairy,  
1103 however, where the protocol is used by a dairy processor, the system description  
1104 would be a description of all the dairies that supply the dairy processor. Similarly,  
1105 where the protocol is integrated into a CF calculator used by a dairy processor, a  
1106 value for  $GHG_{adj_{t(0.6)}}$  would not be presented as is done for the worked examples,  
1107 because the values for  $\hat{y}$  and  $\overline{DQ}$  will be different for each supplier that is analysed.  
1108 In such a case, the report would provide the equation used to calculate  $GHG_{adj_{t(0.6)}}$   
1109 and include any values (*e.g.*  $t_{(0.6,af)}$ ) that are calculated using the **evidence** provided  
1110 in 9.1.

1111

1112 For transparency, where the  $GHG_{adj_{t(0.6)}}$  is incorporated in a CF  
1113 calculator/calculation, the developer of the CF calculator shall make the report  
1114 available to the reviewer of the CF calculator/calculation.

1115

## 1287 DATA QUALITY MATRIX

Data quality category	Description	DQ
<b>Data source</b>	Directly measured	1
	Calculated data based on measurements	1.5
	Calculated data based partly on assumptions	2.5
	Qualified <b>estimation</b> (by experts)	5
	Non-qualified <b>estimation</b>	Not acceptable
<b>System likeness</b>	Data are from the system being assessed by the protocol	1
	Data are from a system or systems with a key variable <sup>+</sup> +/- 5% of the system being assessed by the protocol	1.5
	Data are from a system or systems with a key variable <sup>+</sup> +/- 10% of the system being assessed by the protocol	2
	Data are from a system or systems with a key variable <sup>+</sup> +/- 20% of the system being assessed by the protocol	4
	Data are from a system with unknown key parameters <sup>+</sup>	Not acceptable
<b>Temporal</b>	Less than 1 years old	1
	1 – < 3 years old	2.5
	3 - <6 years old	4
	More than 6 years old	Not acceptable
<b>Geographical</b>	Data from the exact system being assessed by the protocol (location specific)	1
	Data from the same region as the system being assessed	2
	Data from a region with similar production conditions	5
	Data from a region with somewhat similar production conditions	10
	Data from unknown region or region with distinctly different production conditions	Not acceptable

1288 + a key variable is a defining variable for a dairy system (e.g. FPCM output (kg/hd/day, cow number)

1289 APPENDIX C

1290 WORKED EXAMPLE FOR CALCIUM CYANIMIDE (CaCN<sub>2</sub>)

1291

1292 **Preface**

1293

1294 *This worked example demonstrates the application of the protocol to the use of*  
1295 *calcium cyanimide to reduce CH<sub>4</sub> emissions from an anaerobic effluent pond with the*  
1296 *data from a relevant publication used to calculate  $GHG_{adj_{t(0.6)}}$ . Based on current*  
1297 *available **evidence**, **GHG emissions reductions** associated with the use of calcium*  
1298 *cyanimide could not be claimed under the protocol. The reasons for this are:*

- 1299 1. *The use of CaCN<sub>2</sub> does not have regulatory approval in the jurisdiction in which*  
1300 *the dairy system being assessed is located.*
- 1301 2. *There is no full life cycle assessment of CaCN<sub>2</sub> production and use available*
- 1302 3. *Only one **piece of evidence** to support the efficacy of CaCN<sub>2</sub> in reducing CH<sub>4</sub>*  
1303 *emissions from effluent ponds is available (a minimum of 3 are required)*
- 1304 4. *The **experiment** was done in a laboratory setting and there is no **evidence***  
1305 *that the results from this setting were transferable to an effluent pond in a*  
1306 *commercial dairy.*
- 1307 5. *There was no available **evidence** to demonstrate that the efficacy of the CaCN<sub>2</sub>*  
1308 *in reducing **methane** emissions was consistent for longer time periods,*  
1309 *particularly across seasonal conditions.*

1310

1311 *This worked example therefore not only demonstrates how the requirements set out*  
1312 *in the protocol are applied to the **evidence** that demonstrates the efficacy of a*  
1313 ***technology** but also how the equations in the protocol are applied to calculate*  
1314  *$GHG_{adj_{t(0.6)}}$ .*

1315

1316 *This **technology** also has the potential to change to N<sub>2</sub>O emissions from manure and*  
1317 *claimed improvements in fertiliser quality of applied manure would have further*  
1318 *impacts on mitigation potential. There are no available data to incorporate these*  
1319 *factors into the example and, therefore, they are not addressed further here. A full*  
1320 ***LCA** of the product is likely to generate different climate change benefits than those*  
1321 *calculated by the protocol due to the inclusion of the N<sub>2</sub>O emissions.*

1322

1323

## 1324 1 TECHNOLOGY AND IMPLEMENTATION CONTEXT

### 1325 1.1 SCOPE

#### 1326 1.1.1 TECHNOLOGY

1327 The product is a chemical named calcium cyanamide ( $\text{CaCN}_2$ ). Its CAS number is 156-  
1328 62-7.

1329

#### 1330 1.1.2 USE

1331 Calcium cyanimide was included in slurry to reduce  $\text{CH}_4$  emissions from the effluent  
1332 system and will be used throughout the entire year. As per recommendations from  
1333 the manufacturer of the proprietary product Eminex, 1 kg of  $\text{CaCN}_2$  was added for  
1334 each  $\text{m}^3$  of slurry in the pit, with applications repeated every 6 weeks.

1335 Recommendations for use of the proprietary product Eminex can be found online at  
1336 <https://www.alzchem.com/en/brands/eminex/#accordion-3472-item-3>.

1337

#### 1338 1.1.3 SYSTEM

1339 This application of the protocol was specific to the use of  $\text{CaCN}_2$  in a commercial dairy  
1340 that was also used for research and educational purposes. The dairy was located in  
1341 northern Victoria, Australia and receives an average annual rainfall of 556 mm, most  
1342 of which falls in winter. The region has a Mediterranean climate with hot, dry  
1343 summers and cool winters. The soils were variable and include loams and clay. The  
1344 dairy was predominantly a pasture-based system with some supplementation 9  
1345 months a year and a total mixed ration supplied for 3 months (summer). It was a self-  
1346 replacing system and over the year there was an average of 285 Holstein-Friesian  
1347 dairy cattle.

1348

1349 The dairy produced an estimated 109 tonnes of milk solids in 2021 with cows  
1350 averaging 6,669 litres of FPCM per lactation. The diet of milkers was comprised of  
1351 pasture and pellets year-round and high protein hay in spring and summer and silage  
1352 in autumn and winter. Non-milkers were fed pasture and cereal hay in spring with  
1353 pellets added in autumn and winter. Slurry was collected from the milking parlour  
1354 and the barn where animals are housed in the summer, and stored in an anaerobic  
1355 lagoon with a volume of  $10,980\text{m}^3$ . The pond was cleaned out every 4 months.

1356

1357 The efficacy of the **technology** was assumed to be breed, age and weight  
1358 independent.

1359

1360 1.1.4 IMPLEMENTATION PERIOD

1361 Calcium cyanamide was applied to all the manure generated by the animals during  
1362 the summer period.

1363

1364 2 SAFETY

1365

1366 2.1 REGULATORY APPROVALS

1367 Calcium cyanimide did not have approval in the jurisdiction of the assessed system.  
1368 This means  $\text{CaCN}_2$  did not meet the criteria set out in the protocol however it will be  
1369 used as a **technology** to demonstrate the application of the protocol.

1370

1371 It has been approved and available for use in Germany and Austria since late 2021. It  
1372 is rolling out to wider markets in the EU.

1373

1374 2.2 ENVIRONMENTAL IMPACTS

1375 No full life cycle assessment has been performed on Calcium cyanimide. This means  
1376  $\text{CaCN}_2$  did not meet the criteria set out in the protocol. However, it will be used as a  
1377 **technology** to demonstrate the application of the protocol.

1378

1379 A CF of the product Perlka, a  $\text{CaCN}_2$  fertiliser, was completed by Dekra. This product  
1380 had a CF of 2,225 kg  $\text{CO}_2\text{e}$  per tonne of Perlka. As part of this analysis the  
1381 effectiveness of  $\text{CaCN}_2$  as a manure **methane** inhibitor was tested. The emissions  
1382 associated with the production and degradation of the  $\text{CaCN}_2$  product was 27.4 kg  
1383  $\text{CO}_2\text{e}/\text{m}^3$  treated effluent and this resulted in an 87% reduction in emissions  
1384 compared to the reference case where no  $\text{CaCN}_2$  was applied (Schindler, 2021)

1385

1386 Calcium cyanimide is associated with other environmental impacts and results from  
1387 other areas of concern have not been published. It has been used as to sterilise soil  
1388 and on its own has been restricted for use as a fertiliser. This is in part due to risks  
1389 posed to surface water and soils ([see here](#)). The extent of these risks in the **context**  
1390 of use as a manure additive needs to be addressed with a full **LCA**.

1391

1392

1393 -----Mock example only – no actual **LCA** undertaken as yet-----

1394 *An **LCA** was undertaken on manure treatment with and without CaCN<sub>2</sub> for a dairy*  
1395 *production system at a rate of 1 kilogram per cubic meter of effluent being processed*  
1396 *in anaerobic pond system and then land applied.*

1397

1398 *The **LCA** showed that the Climate change benefits are 20% higher than those*  
1399 *calculated via the protocol as the **LCA** included benefits of reduced nitrous oxide as*  
1400 *well as lower **methane** emissions. The addition of calcium cyanamide to manure*  
1401 *treatment leads to 12-fold increase in freshwater ecotoxicity results of manure*  
1402 *treatment process, which translates into a 10% increase to the freshwater ecotoxicity*  
1403 *results for milk utilizing this **technology**. All other indicators showed very little*  
1404 *variation between the system with and without the CaCN<sub>2</sub> treatment.*

1405 -----

1406

1407 2.3 IMPACTS TO THE FARMING SYSTEM

1408 Application of CaCN<sub>2</sub> has been shown to have other beneficial impacts on the farm  
1409 system. The manufacturer reports that there are lower hydrogen sulphide emissions  
1410 from manure with use of the product which improves worker safety. They also claim  
1411 less floating layer formation and lower necessary storage volume and better  
1412 fertilising effect of applying the slurry. It can be applied to the slurry without  
1413 modifications to slurry storage facilities. However, workers need to be careful not to  
1414 touch, breathe or ingest CaCN<sub>2</sub> and use of personal protective equipment is required.  
1415 Environmental effects that could impact on farm productivity would be addressed  
1416 with the required **LCA**.

1417

1418 The only published literature addressing the impacts of CaCN<sub>2</sub> on cattle health,  
1419 welfare, productivity, or **product quality** is an article that confirms that cattle should  
1420 not be directly exposed to CaCN<sub>2</sub> due to the development of dermatitis when added  
1421 to the material spread on the floor (Onda, 2008). Searches of “Calcium cyanamide”  
1422 AND either “animal health” “animal welfare” “milk” or “cattle” were performed in  
1423 Google Scholar and Web of Science. Literature was available to support the hazards  
1424 associated with inhalation and skin contact, use as a pesticide, and fertiliser but  
1425 nothing else specific to impacts on dairy cows or dairy systems, and much of it  
1426 decades old.

1427

1428 3 DEMONSTRATING EFFICACY OF TECHNOLOGY

1429 3.1 Evidence 1

1430 The first **piece of evidence** used to support the **GHG emissions reduction** associated  
1431 with the use calcium cyanimide is Holtkamp et al. (2023). It is an open access article  
1432 with the DOI 10.1016/j.wasman.2023.02.018.

1433

1434 The publication does not meet the requirement that experiments not be conducted  
1435 in a laboratory setting however this **evidence** is included to demonstrate the  
1436 application of the protocol. The publication meets the requirement with respect to  
1437 journal quality. The research was published in the journal Waste Management and  
1438 the article was published in 2023. A search of the Norwegian Register ([results here](#))  
1439 shows that the journal Waste Management was a level 1 journal on the register in  
1440 2023.

1441

1442 3.2 Evidence 2

1443 Not applicable. (*There is only one **piece of evidence** to demonstrate confidence in*  
1444 *calcium cyanimide as **GHG emissions reduction technology**. This means calcium*

1445 *cyanimide does not meet the criteria set out in the protocol however it will be used as*  
1446 *a **technology** to demonstrate the application of the protocol.)*

1447

1448 3.3 Evidence 3

1449 Not applicable.

1450

DRAFT

## 1451 4 DATA QUALITY

1452

1453 When calculating  $GHG_{adj_{t(0.6)}}$  based on the difference between two means, the data  
1454 that are used to calculate the **GHG emissions** for the nominated source are used to  
1455 adjust the calculated **GHG emissions reduction** for **data quality**.

1456

1457 For this worked example, the **GHG emissions** source was **methane** from the dairy  
1458 effluent pond and the calculations used to estimate these emissions in Dairy  
1459 Greenhouse Gas Accounting Framework tool (Eckard, 2020) are sourced from the  
1460 Australian National **GHG** Inventory using the equations below for the dairy location.

1461

1462 *Equation C.1*

1463

$$1464 \quad I = (1.185 + 0.00454W^2 - 0.0000026W^2 + 0.315LWG)^2 \times (MP \times 3.054 \\ 1465 \quad \quad \quad \div 0.6 \div (0.00795 \times DMD - 0.0014) \times 1.1$$

1466

1467 where I is the daily intake, W is the liveweight of animals, LWG is the liveweight gain  
1468 of animals, MP is the milk production and DMD is the dry matter digestibility of the  
1469 intake.

1470

1471 *Equation C.2*

1472

$$1473 \quad M = (I \times (1 - DMD) + (0.04 \times I)) \times 0.0148 \times P$$

1474

1475 Where M is the **methane** produced, VS is the volatile solids that enter the effluent  
1476 system, I is the intake per head per day, DMD is the dry matter digestibility of the  
1477 daily intake and P is the proportion of manure that is diverted to the effluent system.

1478

1479 M is then used to calculate the total **methane** from the animals during the housed  
1480 period.

1481

1482 *Equation C.3*

1483

$$1484 \quad Total\ M = M \times N \times D$$

1485

1486 where Total M is the total **methane** emitted during the period (D) for the number of  
1487 cattle (N) housed.

1488 The variables that are required to calculate **methane** from the manure management  
 1489 system are those included in the equations above as presented in Table C.1.

1490

1491 *Table C.1 Variables, their values, units, data source and the quality of data used.*

Variable	Value	Unit	Data source	Data quality (A, S, T, G)
Liveweight	640	Kg	Averages calculated from measurements	1.5,1,2.5,1
Liveweight gain	0	Kg/hd/day	Calculated from measurements	1.5,1,2.5,1
Dry matter digestibility	70	%	Converted from metabolizable energy of intake	5, 4, 1, 5
Animal numbers	300	Number	Measured	1,1,2.5,1
Proportion of manure captured by effluent system	100	%	Estimated due to animals being housed	1,1,2.5,1
Milk production	25	L/hd/day	Measured	1,1,2.5,1

1492

1493 Animal numbers, liveweight, liveweight gain, milk production, and proportion of  
 1494 manure captured by the effluent system had similar **data quality** values. The values  
 1495 were direct measures or calculated based on measurements (Data source), came  
 1496 from the system being assessed (System likeness), were 2 years old (Temporal) and  
 1497 were from the exact system being assessed (Geographical).

1498

1499 Dry matter digestibility (DMD) was calculated from several data sources. The  
 1500 concentrations of various feed types and their DMD were based primarily on on-farm  
 1501 data and results of feed tests. However, pasture DMD was based on values from the  
 1502 Australian National Greenhouse Gas Inventory which use an estimate of DMD from a  
 1503 stratified random sample of Australian dairy farms published in 2012 (n=41; Christie  
 1504 2012). This gave a DQ of 5 for a qualified estimate. The systems included in that  
 1505 analysis were quite variable in milk production giving a value of 4 for system likeness.  
 1506 Although the study used was over 10 years old, the data were used in the most  
 1507 recent National Greenhouse Gas Inventory, hence it was assumed to be less than 1  
 1508 year old (T = 1) and is applicable to national level assessments (G = 5).

1509

1510 **Data quality** was calculated using Equation 6 of the protocol based on values in  
1511 **Error! Reference source not found.** (Equation C.4)

1512  
1513 *Equation C.4*

$$\begin{aligned} 1514 \quad \overline{DQ} &= \frac{\sum_{i=1}^n D_i + S_i + T_i + G_i}{n \times 4} \\ 1515 \quad &= \frac{(1.5+1+2.5+1) + (1.5+1+2.5+1) + (5+4+1+5) + (1+1+2.5+1) + (1+1+2.5+1) + (1+1+2.5+1)}{6 \times 4} \\ 1516 \quad &= 1.5 \end{aligned}$$

1517

## 1518 5 CALCULATION OF GHG EMISSIONS REDUCTION

### 1519 5.1 EVIDENCE USED FOR CALCULATIONS

1520 The publication used for calculations was Holtkamp et al. (2023) as described earlier.  
1521 Standard errors were not provided in the text of the publication so were inferred  
1522 from published graphs. This has been done to enable the demonstration of the  
1523 application of the protocol. Use of this data in the protocol would require that  
1524 standard errors of the mean values were reported in written form. The publication  
1525 meets requirements for **evidence** as outlined in the previous section.

1526

1527 The use of CaCN<sub>2</sub> in the system being assessed (*i.e.* the CaCN<sub>2</sub> was added to slurry)  
1528 was the same as that used in Holtkamp et al. (2023) and the concentration of CaCN<sub>2</sub>  
1529 added was consistent with the rate applied in Holtkamp et al. (2023).

1530

1531 There was a lack of **evidence** to support consistent effectiveness of CaCN<sub>2</sub> across all  
1532 seasons where properties of the effluent pond such as water temperature are likely  
1533 to change. There was also no **evidence** to support an absence of adaptation of the  
1534 microbial population to the use of CaCN<sub>2</sub>. For the purposes of this worked example, it  
1535 was assumed that the reductions reported in Holtkamp et al. (2023) were  
1536 representative of reductions that occur year-round as long as the instructions for the  
1537 product “Eminex” were followed for the entire implementation period.

1538

1539 The research used to support calculations is from a laboratory-based **experiment**  
1540 using sealed flasks containing a litre of effluent. The application of this data to a  
1541 commercial dairy effluent system cannot be justified due to differences such as the  
1542 volume of the effluent, daily additions of material to the effluent pond and the  
1543 change in the composition of effluent added to the system. The research was used  
1544 for this worked example to demonstrate the application of the protocol.

1545

1546 5.2 EQUATIONS

1547 Equations from section 9.3.1 were used to calculate  $GHG_{adj_{t(0.6)}}$  for CH<sub>4</sub> emissions  
 1548 from dairy slurry in the system being assessed.

1549

1550 Values required to perform calculations are presented in Table C.2 below.

1551

1552 *Table C.2 Symbols used in equations in the protocol, their description and values for the*  
 1553 *CaCN<sub>2</sub> worked example. Values followed by \* were inferred from graphs in the publication.*

Symbol	Description	Value
$\bar{x}_c$	Mean of control group	669
$\bar{x}_t$	Mean of treatment group	3
$SE_{\bar{x}_c}$	Standard error of control group	340*
$SE_{\bar{x}_t}$	Standard error of treatment group	1.5*
$df_{\bar{x}_c}$	Degrees of freedom for the control group	3
$df_{\bar{x}_t}$	Degrees of freedom for the treatment group	3
$n$	Number of data variables required to calculate <b>data quality</b>	6
$t_{(0.6,4)}$	Critical $t$ -score for 60% chance of exceedance with 4 degrees of freedom	-0.27

1554

1555 Populating the equations from the protocol with the values from section 9.3.1  
 1556 resulted in the following (note that equation number refers to the number in the  
 1557 protocol).

1558

1559 *Equation C.5*

$$1560 \Delta_{diff} = \sqrt{DQ(SE_{\bar{x}_c}^2 + SE_{\bar{x}_t}^2)} = \sqrt{1.5 \times (340^2 + 1.5^2)} = 430$$

1561

1562 *Equation C.6*

$$1563 df = \frac{(SE_{\bar{x}_c}^2 + SE_{\bar{x}_t}^2)^2}{\left(\frac{SE_{\bar{x}_c}^4}{df_{\bar{x}_c}} + \frac{SE_{\bar{x}_t}^4}{df_{\bar{x}_t}}\right)} = \frac{(340^2 + 1.5^2)^2}{\left(\frac{340^4}{3} + \frac{1.5^4}{3}\right)} = 3$$

1564

1565

1566 *Equation C.7*

$$1567 \bar{x}_d = \bar{x}_c - \bar{x}_t = 669 - 3 = 666$$

1568

1569 Results from Equation C.5 to Equation C.7 are then used to populate Equation C.8.

1570

1571 *Equation C.8*

1572

1573  $x_a = \bar{x}_d + t_{(0.6,4)} \cdot \Delta_{diff} = 666 + -0.27 \times 430 = 550$

1574

1575 Finally, results from Equation C.8 are used to populate Equation C.9.

1576

1577 *Equation C.9*

1578  $GHG_{adj_{t(0.6)}} = \frac{\bar{x}_c - x_a}{\bar{x}} = \frac{669 - 550}{669} = 0.18$

1579

1580

## 1581 6 Application of $GHG_{adj_{t(0.6)}}$

1582 *Note that this section is for reference only and is not required to be included in a*  
1583 *report produced by the use of the protocol*

1584

1585 A CF of the system being assessed was calculated using the Dairy Greenhouse Gas  
1586 Accounting Framework tool (Eckard, 2020). A total of 347 t CO<sub>2</sub>e of **methane** were  
1587 emitted by manure from cattle housed in the dairy during the summer period.

1588 Multiplying the effluent **methane** over the summer period by  $GHG_{adj_{t(0.6)}}$  resulted in  
1589 effluent **methane** emissions of 63 t CO<sub>2</sub>e. The CF of the dairy can then be re-  
1590 calculated by replacing the original value with the adjusted value. By subtracting the  
1591 adjusted value from the original value, we can claim an **emissions reduction** of 271 t  
1592 CO<sub>2</sub>e from **methane** over the summer period when the animals were fully housed.

1593

1594

1595

## 1596 APPENDIX D

### 1597 WORKED EXAMPLE OF PROTOCOL FOR 3- NITROOXYPROPANOL

1598

#### 1599 *Preface*

1600

1601 *This worked example demonstrates the application of the protocol to the use of 3-*  
1602 *nitrooxypropanol (3-NOP) to reduce enteric CH<sub>4</sub> emissions from dairy cattle, with the*  
1603 *data from a relevant publication used to calculate  $GHG_{adj_{t(0.6)}}$ . Based on current*  
1604 *available **evidence**, **GHG emissions reductions** associated with the use of 3-NOP*  
1605 *could not be claimed under the protocol for the system being assessed because there*  
1606 *is no life cycle assessment compliant with requirements set out in the protocol.*

1607

1608 *This worked example demonstrates how the equations in the protocol are applied to*  
1609 *calculate  $GHG_{adj_{t(0.6)}}$  and also how the requirements set out in the protocol are*  
1610 *applied to the **evidence** that demonstrates the efficacy of a **technology**.*

1611

## 1612 1 TECHNOLOGY AND IMPLEMENTATION CONTEXT

1613

### 1614 1.1 SCOPE

#### 1615 1.1.1 TECHNOLOGY

1616 The product is a chemical named 3-nitrooxypropanol, or 3-NOP. Its CAS number is  
1617 100502-66-7. This is a proprietary **technology** owned by DSM, who markets the  
1618 product under the name “Bovaer”.

1619

#### 1620 1.1.2 USE

1621 The 3-NOP feed additive will be included in total mixed rations at a rate of 80 mg/kg  
1622 DMI that will be mixed with a pre-mixed ration during manufacture.

1623 Supplementation will occur in the summer months when housed animals have ad-lib  
1624 access to a total mixed ration.

1625

#### 1626 1.1.3 SYSTEM

1627 This application of the protocol was specific to the use of 3-NOP in a commercial  
1628 dairy that was also used for research and educational purposes. The dairy was  
1629 located in northern Victoria, Australia and receives an average annual rainfall of 556  
1630 mm, most of which falls in winter. The region has a Mediterranean climate with hot,  
1631 dry summers and cool winters. The soils were variable and include loams and clay.

1632 The dairy was predominantly a pasture-based system with some supplementation 9  
1633 months a year and a total mixed ration supplied for 3 months (summer). It was a self-  
1634 replacing system and over the year there was an average of 285 Holstein-Friesian  
1635 dairy cattle.

1636

1637 The dairy produced an estimated 109 tonnes of milk solids in 2021 with cows  
1638 averaging 6,669 litres of FPCM per lactation. The diet of milkers was comprised of  
1639 pasture and pellets year-round and high protein hay in spring and summer and silage  
1640 in autumn and winter. Non-milkers were fed pasture and cereal hay in spring with  
1641 pellets added in autumn and winter. The total mixed ration was a mix of commercial  
1642 dairy pellets and pasture silage.

1643

1644 The **technology** was assumed to be breed independent and age and weight  
1645 independent.

1646

#### 1647 1.1.4 IMPLEMENTATION PERIOD

1648 The cattle received the supplement during the 3 months of summer when they were  
1649 housed.

## 1650 2 SAFETY

### 1651 2.1 REGULATORY APPROVALS

1652 The use of 3-NOP has been approved in the European Union at 53 to 80 mg active  
1653 substance/ kg of complete feed with 12% moisture content. It was demonstrated  
1654 that 3-NOP and its metabolites had no mutagenic or genotoxic potential (Thiel,  
1655 2019b). The primary safety concern with 3-NOP is risks to the users of the product as  
1656 it was considered an irritant to eyes and skin and is harmful if inhaled. To minimise  
1657 these risks the additive will be available in granular form with negligible content of  
1658 inhalable particles. Use of personal protective equipment is required to prevent  
1659 contact with eyes or skin (2022)

1660

1661 In the **context** of this use, there is approval for commercial use of 3-NOP in Australia  
1662 (Byrne, 2022; DSM, 2024) as long as claims of productivity or health benefits are not  
1663 made.

1664

1665 2.2 ENVIRONMENTAL IMPACTS

1666 The European Food Safety Authority concluded that 3-NOP does not have an adverse  
1667 effect on consumer safety or the environment (2022) and there is no concern over  
1668 residues being introduced to the environment or **farming system**(EFSA Panel on  
1669 Additives Products or Substances used in Animal Feed (FEEDAP), 2021).

1670

1671 A **LCA** using data from the manufacturer (DSM) on the climate impacts of 3-NOP  
1672 production was included in an unpublished analysis (Kebreab, 2021). It found that  
1673 the production of and shipping of 3-NOP in California had negligible impact on the  
1674 total **emissions reduction** achieved by supplementing dairy diets in California with 3-  
1675 NOP. An analysis using similar methodology covering the entire US was published in  
1676 2022. Although there was large variability between regions, use of 3-NOP reduced  
1677 emissions intensity (kg fat protein corrected milk) by 12%, including emissions  
1678 associated with production and transport of feed additives (Uddin et al 2022).  
1679 However, a complete **LCA** of 3-NOP production including all impact categories has  
1680 not been done. Therefore, 3-NOP does not comply with the protocol. Nevertheless,  
1681 we have continued to work through the protocol using 3-NOP for the purposes of  
1682 providing a complete example.

1683

1684 A **LCA** of 3-NOP would require impact results based on APPENDIX E.

1685

1686 It expected that the interpretation of the **LCA** might be something like.

1687

1688 -----*Mock example only – no actual **LCA** undertaken as yet*-----

1689 *An **LCA** was undertaken on Milk production with and without 3-NOP for a generic*  
1690 *production system in Europe and it shows that the Climate change benefits calculated*  
1691 *in the **LCA** are slightly higher than those calculated via the protocol due to the*  
1692 ***conservative data quality** corrections included in the protocol. There was no*  
1693 *significant change in eutrophication, water scarcity, land use or soil quality impact.*  
1694 *The resource depletion (fossil fuels) is 3% higher for the system using 3-NOP due to*  
1695 *manufacturing impacts of the supplement.*

1696 -----

1697

1698 2.3 IMPACTS TO THE FARMING SYSTEM

1699 There have been several studies that investigate the impact of 3-NOP on milk  
1700 production, composition, and quality. Less published information is available on  
1701 factors specific to animal health or welfare.

1702

1703 The literature summarised was found through searching Google Scholar and Web of  
1704 Science for the terms (3-NOP and milk quality) or (3-NOP AND dairy AND either  
1705 health, welfare OR production).

1706

1707 Published literature has shown no or minor effects on productivity . Several studies  
1708 show no impact on DMI or milk production(van Gastelen, 2020; Van Wesemael,  
1709 2019). There is some **evidence** for decreases in milk yield (Maigaard et al 2024)  
1710 which has been observed in animals on a higher 3-NOP dose (60 vs 80 mg/kg DM)  
1711 (van Gastelen et al., 2022) and dairy cows on high concentrate diets (Schilde, 2021b).

1712

1713 In terms of composition and quality, 3-NOP is metabolised into endogenous  
1714 compounds and presence of exogenous residues in the milk is unlikely. (Thiel,  
1715 2019a). An increase in milk fat has been observed (van Gastelen et al., 2022) but this  
1716 is not consistent across studies (van Gastelen, 2020; Van Wesemael, 2019). Two  
1717 studies have reported a significant increase in milk urea nitrogen with the use of 3-  
1718 NOP (Melgar, 2021; Schilde, 2021a), . An overview of reviewed studies focusing on  
1719 dairy cows is provided in Table D.1.

1720

1721 *Table D.1 Published studies on 3-NOP and the impacts on dairy cattle welfare, feed*  
1722 *intake/efficiency, milk production and/or milk composition.*

Citation	Health/ Welfare topics	Intake/ Feed efficiency	Milk production	Milk composition/ quality
Garcia et al. (2022)	shifted rumen fermentation from acetate to propionate			
Jayanegara et al. (2018)	decreased total VFA concentration in the rumen	No impacts on DMI	Decrease in milk production (not statistically significant)	No change
Kim et al. (2020)	Decreased % acetate and increase in valerate in rumen	No change in DMI	Decrease in milk production (not statistically significant)	Increase milk fat and protein (not statistically significant)
Kjeldsen et al. (2023)	VFA concentrations in the rumen negatively affected, decreased acetate, & increased concentrations of several alcohols in the rumen.	Decrease in DMI (11%)	--	--
Maigaard et al. (2023)	--	Decrease in DMI (13%)	Decrease in ECM (9% in)	--
Melgar et al. (2020a)	No change in weight, condition, hormones except a decrease in insulin, no impact on postpartum resumption of ovarian activity	No change (as % body mass), no change in feed efficiency	No change in milk or ECM	Only an increase in short-chain fatty acids, no change in sensory properties of milk or cheese

Melgar (2021)	--	No change in feed efficiency	No change in milk or ECM yields	Increased milk fat and milk urea N concentration
Melgar et al. (2020b)	--	No change in DMI	No change in milk yield	Increase in fat concentration, <i>tend</i> to increase milk urea N
Schilde (2021a)	No changes to rumen pH but 3-NOP with high concentrated diet had a more propionic-metabolic profile	--	Decrease in ECM in cows on high concentrate diet, not in other cows	Milk lactose and milk urea increased
Schilde et al. (2022)	3-NOP improved the energy budget of dairy cows; no effect on lipomobilization in adipose deposits, and lower serum non-esterified fatty acid conc.			
van Gastelen (2020)	Increased digestibility of several nutrients, animals on 3-NOP gained more weight	No change in DMI or feed efficiency,	No change in milk yield	Addresses impacts on several fatty acids. Overall no change in milk composition.
van Gastelen et al. (2022)	--	Decrease in DMI, no change in feed efficiency	Depended on 3NOP dose. No change in milk yield with 60 mg 3NOP/ kg of DM, decline with 80 mg 3NOP/ kg DM	Depended on 3NOP dose. No change with 60 mg 3NOP/ kg of DM, decline in major components with 80 mg 3NOP/ kg DM

Van Wesemael et al. (2019)	--	No change in DMI	No change in milk yield	No change in composition
----------------------------	----	------------------	-------------------------	--------------------------

1723

1724 The European Food Safety Authority concluded that 3-NOP consumption does not  
 1725 have an adverse effect on dairy cows (European Union, 2022). Trials in beef  
 1726 feedstock observed animal using the DART system and found no evidence of welfare  
 1727 impacts (Alemu et al., 2021). Similar animal welfare information for dairy systems is  
 1728 has not been published. More information on the potential impacts of 3-NOP on the  
 1729 rumen of dairy cows is available (Pitta, 2022; Schilde, 2021b).

### 1730 3 DEMONSTRATING CONFIDENCE IN TECHNOLOGY

1731 *Under the requirements of the protocol, only one **piece of evidence** is required to*  
 1732 *demonstrate confidence in the efficacy of 3-NOP when the **piece of evidence** is a*  
 1733 ***meta-analysis**.*

1734

#### 1735 3.1 Evidence 1

1736 Meta analysis undertaken by Kebreab et al. (2023) which assessed the reduction in  
 1737 **enteric methane** associated with feeding 3-NOP. The studies that were included in  
 1738 the analysis by Kebreab et al. (2023) were not conducted in commercial or research  
 1739 dairies. They were appropriate studies to demonstrate confidence in this **technology**  
 1740 because measuring **enteric methane** accurately requires animals are housed in  
 1741 respiration chambers.

1742

1743 The publication was published in the Journal of Dairy Science in 2023, that was a  
 1744 Level 2 journal on the Norwegian Register For Scientific Journals, Series and  
 1745 Publishers at the time of publication. This was demonstrated at this [link](#).

1746

1747 All studies used included in the **meta-analysis** had controls groups.

1748

1749 Kebreab et al. (2023) is an open-access publication with a DOI of 10.3168/jds.2022-  
1750 22211.

## 1751 4 DATA QUALITY

1752

1753 *Table D.2 Variables and their units, data source and the quality of data used.*

Variable	Value	Unit	Data source	Average data quality (D, S, T, G)
3-NOP	80	mg/kg DM	Feed supplier	1.00 (1,1,1,1)
Crude fat	27.1	% DM	Estimated from feed tests	1.13 (1,1.5,1,1)
NDF	26.5	% DM	Estimated from feed tests	1.13 (1,1.5,1,1)
Starch	2.8	% DM	Estimated from research article	2 (1,1,4,1)

1754

1755 For **context**, 3-NOP intake was based on the average concentration in the purchased  
1756 ration, crude fat and NDF intake were based on quality assessments of the feeds in  
1757 the ration and the starch content of the feeds was obtained from published  
1758 literature. Thus starch content has the lowest **data quality** rating used for the **data**  
1759 **quality** assessment.

1760

1761 **Data quality** was calculated using Equation 6 of the protocol based on values in Table  
1762 D.2.

1763

1764 *Equation D.1*

$$\begin{aligned} 1765 \quad \overline{DQ} &= \frac{\sum_{i=1}^n D_i + S_i + T_i + G_i}{n \times 4} \\ 1766 \quad &= \frac{(1+1+1+1) + (1.5+1+1+1) + (1.5+1+1+1) + (1+1+4+1)}{4 \times 4} \\ 1767 \quad &= 1.3 \\ 1768 \end{aligned}$$

## 1769 5 CALCULATION OF GHG EMISSIONS REDUCTION

### 1770 5.1 EVIDENCE USED FOR CALCULATIONS

1771 The **evidence** used for calculations is the equation developed using meta-regression  
1772 published by Kebreab et al. (2023) with a DOI of 10.3168/jds.2022-22211.

1773

1774 Kebreab et al. (2023) did not address the duration of the effectiveness of 3-NOP  
1775 when fed continuously. Studies of 3-NOP have reported different responses between  
1776 species of ruminal methanogen (Duin et al., 2016; Pitta et al., 2021) and **evidence**  
1777 (Vyas et al., 2018) suggesting that over time the rumen adapts to 3-NOP and the  
1778 dominant species of methanogens changes. This can lead to a reduction in the  
1779 efficacy of 3-NOP in reducing **enteric methane**. Research has yet to determine the  
1780 factors that regulate rumen adaptation to 3-NOP and **enteric methane** emissions  
1781 increase relative to the start of 3-NOP use. However, a study (Schilde, 2021a) has  
1782 demonstrated that rumen adaptation in dairy cattle did not occur over a 148 day  
1783 period of feeding. The period for which 3-NOP was fed to dairy cattle was summer in  
1784 Australia (*i.e.* December – February), a total of 90 days, was less than the 148 days in  
1785 (Schilde, 2021a) so a reduction in enteric CH<sub>4</sub> reduction was claimed for the entire  
1786 duration of animals being housed.

1787

1788 Kebreab et al. (2023) is a **meta-analysis** that examined the reduction in **enteric**  
1789 **methane** associated with 3-NOP used in barn-housed total mixed ration systems in  
1790 different locations. The system being assessed is barn-housed during the summer  
1791 period where animals are fed a total mixed ration so **emissions reductions** could only  
1792 be claimed for that period as Kebreab et al. (2023) was not relevant to pasture-based  
1793 production.

1794

1795 The studies used in the **meta-analysis** used animal chambers or sulphur hexafluoride  
1796 to estimate **enteric methane** emissions from animals. The known relationship  
1797 between intake and **enteric methane** provides confidence that the results from the  
1798 experiments used in the **meta-analysis** are relevant to a commercial dairy. As such,  
1799 there was a high degree of confidence that the equation from Kebreab et al. (2023)  
1800 would be suitable to estimate reduction in **enteric methane** when implemented in  
1801 the system being assessed here.

1802

### 1803 5.2 EQUATIONS

1804 Kebreab et al. (2023) conducted a meta-regression to examine relationships between  
1805 feed quality variables, 3-NOP and CH<sub>4</sub> yield and then used leave-one-out cross  
1806 validation (LOOCV) to determine the model that explained the most variation.

1807

1808 The equation from Kebreab et al. (2023) used to calculate  $\hat{y}$  for the calculation of a  
1809 **prediction interval** was;

1810

1811 *Equation D.2*

$$\begin{aligned} 1812 \Delta \text{CH}_4 \text{ yield (\%)} &= -30.8 - 0.226 \times (3\text{-NOP} - 70.5) + 0.906 \times (\text{NDF} - 32.9) + 3.871 \times \\ 1813 &(\text{crude fat} - 4.2) - 0.337 \times (\text{starch} - 21.1) \\ 1814 &= -30.8 - 0.226 \times (80 - 70.5) + 0.906 \times (26.5 - 32.9) + 3.871 \times (2.8 - 4.2) - 0.337 \times \\ 1815 &(27.1 - 21.1) \\ 1816 &= -46.2 \end{aligned}$$

1817

1818 where 3-NOP = 3-nitroxypropanol dose (mg/kg of DM), and NDF, crude fat, and  
1819 starch are in % DM.

1820

1821 *Equation D.3*

$$1822 PI = \hat{y} \pm t_{1-\alpha, k-2} \cdot \sqrt{MSE(1 + \mathbf{x}^T(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{x})}$$

1823

1824 is the equation to calculate **prediction intervals** for multiple linear regression  
1825 developed using a meta-regression analysis where  $t_{1-\alpha, k-2}$  is the critical  $t$ -score for  
1826 the relevant  $\alpha$  with  $k$  cases,  $MSE$  is the mean square error of the regression  
1827 equation,  $\mathbf{x}$  and  $\mathbf{X}$  are matrices of the values that are used to populate the equation  
1828 to calculate  $\hat{y}$  and the design matrix of the regression equation, respectively, and  $\mathbf{x}^T$   
1829 and  $\mathbf{X}^T$  are  $\mathbf{x}$  and  $\mathbf{X}$  transposed.

1830

1831 *Equation D.4*

$$1832 PI = \hat{y} \pm t_{1-\alpha, k-2} \cdot RMSE$$

1833

1834 *Equation D.5*

$$1835 \hat{y}_{adj} = \hat{y} \pm t_{1-\alpha, k-2} \cdot \overline{DQ} \cdot RMSE$$

1836

1837 Kebreab et al. (2023) did not report **prediction intervals** from the LOOCV and the  
1838 design matrix of the regression equation was not available, however Kebreab et al.  
1839 (2023) did report the RMSE of Equation D.2 developed using the LOOCV analysis.  
1840 Hence, it was not possible to use Equation D.3 to calculate the prediction interval  
1841 and instead Equation D.4, that is generally regarded as being suitable to calculate a  
1842 **prediction interval**, was used as the basis for calculating the **prediction interval**.  
1843 Integrating the **data quality** adjustment into Equation D.4 **Error! Reference source**  
1844 **not found.** resulted in Equation D.5.

1845

1846 *Equation D.6*

$$1847 \quad GHG_{adj_{t(0.6)}} = \frac{\hat{y}_{adj}}{r\%} + 1 = \frac{\hat{y} \pm t_{1-\alpha, k-2} \cdot \overline{DQ} \cdot RMSE}{100} + 1 = \frac{-46.2 \pm 0.256 \times \sqrt{1.3 \times 51.1}}{100} + 1$$

1848

1849 *Equation D.7*

1850

$$1851 \quad GHG_{adj_{t(0.6)}} = \frac{(-44.1, -48.3)}{100} + 1$$

1852

1853 *Equation D.8*

$$1854 \quad GHG_{adj_{t(0.6)}} = \frac{-44.1}{100} + 1 = 0.56$$

1855

1856

1857 The dependent variable of the equation from Kebreab et al. (2023) was an **emissions**  
1858 **reduction** relative to a control and a negative value (*i.e.* the unadjusted value for  $\hat{y}$  of  
1859 -46.1 indicated that **enteric methane** emissions would be 53.8% lower than a control  
1860 treatment based on the data used to populate **Error! Reference source not found.**),  
1861 hence the appropriate equation to calculate  $GHG_{adj_{t(0.6)}}$  from the protocol was  
1862 Equation 7.

1863 Equation D.6 shows Equation 7 of the protocol populated with the relevant equation  
1864 for  $\hat{y}_{adj}$  and populated with the relevant critical  $t$ -score, RMSE from Kebreab et al.  
1865 (2023) and **data quality**, as calculated above. Populating Equation D.6 resulted in two  
1866 values for  $\hat{y}_{adj}$  (Equation D.7) and, consistent with section 9.2.2 of the protocol that  
1867 states the **prediction interval** that results in a value for  $\hat{y}_{adj}$  being greater than the  
1868 value for  $\hat{y}$  shall be used, a value of -44.1 was chosen that resulted in a  $GHG_{adj_{t(0.6)}}$   
1869 of 0.56 (Equation D.8).

1870

## 1871 6 Application of $GHG_{adj_{t(0.6)}}$

1872 *Note that this section is for reference only and is not required to be included in a*  
1873 *report produced by the use of the protocol*

1874

1875 A CF of the dairy under study was calculated using the Dairy Greenhouse Gas  
1876 Accounting Framework tool (Eckard, 2020). A baseline total of 6 454 kg CO<sub>2</sub>-e of  
1877 **enteric methane** were emitted by dairy cows housed in the dairy during the summer  
1878 period. When 3-NOP was fed to these animals that resulted in **enteric methane**

1879 emissions of 3 614 kg CO<sub>2</sub>-e. The CF of the dairy production can be recalculated by  
1880 replacing the baseline value of 6 454 kg CO<sub>2</sub>-e with 3 614 kg CO<sub>2</sub>-e for **enteric**  
1881 **methane**. Subtracting the adjusted **GHG emissions** for **enteric methane** from the  
1882 baseline **enteric methane** value gives a claimable **GHG emissions reduction** of 2840  
1883 kg CO<sub>2</sub>-e.

DRAFT

## APPENDIX E

Table E.1 Impact categories recommended for the **LCA**. Other impact categories should be used where they are relevant to the **technology**.

Impact category	Recommended method	Rationale
Climate change	<b>IPCC GWP 100 AR6</b> or more recent updates	The basis of the <b>GHG abatement</b>
Resource use- fossil	Frischknecht et al. (2003) or similar	Production energy requirement for the supplement
Ozone depletion potential	Chanin et al. (1999)	Included due to ozone depleting impact of bromoform (CH <sub>3</sub> Br)
Freshwater Eutrophication	Payen et al. (2021)	Growing <i>Asparagopsis</i> to produce a bromoform based <b>enteric methane</b> inhibitor may involve emission of nutrient rich water from growing systems
Water scarcity	Boulay et al. (2018)	Changes in productivity are possible which may affect water embodied in feed production.
Land use impacts on ecosystem services	Brandão et al. (2011) or similar	Changes in productivity are possible which may affect land demand for feed. .
Ecotoxicity and Human toxicity	Fantke et al. (2021)	Bromoform has a freshwater ecotoxicity effect and CF value for human toxicity – non cancer.

## APPENDIX F

[RECOMMENDATIONS FOR FUTURE RESEARCH AND USERS OF PROTOCOL – TO B E COMPLETED]
